# ABSTRACT

Obliquely propagating nonlinear fast and slow magnetosonic wave modes in a hot non-Maxwellian dissipative plasma are investigated in the current work. Modified temperatures have been derived for the non-extensive *Q*- and (*r, q*)-distributions that correspond to the physical properties of such non-Maxwellian plasmas. The reductive perturbation technique has been employed to derive the linear dispersion relation (LDR) and Kadomstev-Petvashvilli-Burgers (KPB) equation for slow and fast magnetosonic wave modes in two dimensions. We then investigated the effect of non-extensive parameter  $Q$ , spectral indices  $(r, q)$  and kinematic viscosity  $\nu$  on the LDR and nonlinear propagation of KPB shock profiles for both the slow and fast mode magnetosonic waves. We found that linear and nonlinear propagation of fast and slow magnetosonic wave modes have been considerably modified in such non-Maxwellian plasmas. The results presented here would depict a realistic picture of the propagation of linear and nonlinear fast and slow magnetosonic wave modes in non-Maxwellian plasmas.

## **Introduction**

A significant amount of research has been carried out since the discovery of magnetosonic waves in the fields of observations, theoretical investigations and simulations  $[1-9]$  $[1-9]$ . In the magnetohydrodynamic (MHD) picture, fast and slow modes of magnetosonic waves are the fundamental low frequency modes in magnetized plasma [\[10](#page-8-0)–13]. In addition to these low frequency modes, in ideal MHD when heat conduction is added, there are two other roots as well, called entropy modes, characterized by non-propagating perturbations of thermodynamical properties of plasma with almost zero frequency [\[14\].](#page-8-0) Propagation of magnetosonic solitary waves has been the subject of interest for many researchers due to their importance in particle acceleration and heating in fusion devices, space and astrophysical plasmas. Boardsen et al. [\[2\]](#page-8-0) observed the fast magnetosonic waves at large angles to the ambient magnetic field at the magnetic equator associated with the proton ring distributions. In the Earth's magnetosphere, Horne et al. [\[3\]](#page-8-0)  investigated the generation, growth and decay of radially propagating fast magnetosonic waves and found that protons are heated as a result of these waves. Fast magnetosonic waves have also been found to be responsible for electron heating and are thought to play an important role in the dynamics of radiation belts [\[4\]](#page-8-0). Intense magnetosonic waves have been observed in the plasma sphere associated with the proton ring distributions which provide the free energy for their excitations [\[5\].](#page-8-0)

Shah and Bruno [\[1\]](#page-8-0) investigated obliquely propagating fast and slow magnetosonic modes in a hot plasma and derived the KadomstevPetvashvilli (KP) equation for arbitrary plasma beta. Mushtaq and Shah [\[10\]](#page-8-0) studied nonlinear magnetosonic waves propagating obliquely to the external magnetic field in electron–positron-ion (*epi*) plasma and considered the effect of plasma beta on the propagation of fast and slow modes. Chakrborty and Das [\[11\]](#page-8-0) studied the effect of finite Larmor radius on the oblique propagation of magnetosonic waves and where it was shown that these waves are governed by KP equation in a collisionless plasma with an additional dispersive term. Magnetosonic waves have also been studied using quantum-hydrodynamic (QHD) model in a dense plasma and where both the hump and dip soliton structures, were investigated for various plasma parameters [\[12\]](#page-8-0). The KP and cylindrical Kadomtsev-Petviashili-Burgers (CKPB) equations have been derived for nonlinear magnetosonic waves in quantum dusty magnetized plasmas [\[15,16\].](#page-8-0)

In theoretical studies on the nonlinear magnetosonic waves mentioned above, collisions have been ignored which may occur between neutrals and charged particles as well as between charged particles [\[13\].](#page-8-0) Due to collisions (or any kind of dissipation) in various laboratory and space plasmas, the nonlinear evolution of magnetosonic waves modifies significantly. In a collisional plasma, one-dimensional propagation of magnetosonic waves has been governed by Kortewegde Vries-Burger's (KdV-B) equation [\[17\].](#page-8-0) In a two-dimensional warm collisional plasma, obliquely propagating magnetosonic waves have been governed by Kadomstev-Petvashvilli-Burger's (KPB) equation [\[18,19\].](#page-8-0) In a dusty of inertialess electrons and ions and here it is shown that these waves are governed by the modified Korteweg-de Vries

<span id="page-1-0"></span>(mKdV) equation [\[20\]](#page-8-0). Later, dissipative structures have been obtained by studying nonlinear magnetosonic waves in a pair-ion plasma in the presence of ion–electron collisions [\[21\]](#page-8-0). Considering ion-neutral collisions, the damped Korteweg-de Vries (DKdV) equation has been obtained for perpendicularly propagating magnetosonic waves and characteristics of damped soliton structures were examined [22–[23\].](#page-8-0)

#### **Distribution function and modified temperature**

It is well known that space plasmas are tenuous and collisionless, therefore observations of distribution functions from various regions including solar wind and Earth's magnetosphere, generally exhibit nonthermal features such as high energy tail [\[24](#page-8-0)–27] and flat top or spiky nature at low energies [28–[31\]](#page-8-0). Distributions with high energy tail and Gaussian peak are well modeled with power law kappa (*κ*) distribution function, where  $\kappa$  index measures the strength of the high energy tail. For *κ*→∞, the distribution approaches a Maxwellian. However, when the observed distributions exhibit flat top or spike at low energies, the double spectral index distribution, i.e. the generalized  $(r, q)$  distribution function becomes the ultimate choice [\[32\].](#page-8-0) In the limiting cases,  $r = 0, q \rightarrow \infty$  and  $r = 0, q \rightarrow (\kappa + 1)$ , Maxwellian and kappa distributions can be recovered from  $(r, q)$  distribution, respectively. Recently,  $(r, q)$ distribution has been employed in numerous studies and the results have shown that these are significantly improved both qualitatively and quantitatively  $[33-38]$  $[33-38]$ . Thus  $(r, q)$  distribution has stimulated new avenues for studying the linear and nonlinear waves which are significantly different from the standard Maxwellian and power law distributions. The three-dimensional  $(r, q)$  distribution function has the form

$$
f_{rq}(v) = \frac{3\Gamma(q)(q-1)^{-3/(2+2r)}}{4\pi (A2T/m)^{3/2}\Gamma(q-\frac{3}{2+2r})\Gamma(1+\frac{3}{2+2r})}\left(1+\frac{1}{q-1}\left[\frac{v^2}{V_{th}^2}\right]^{1+r}\right)^{-q}
$$
\n(1)

where

$$
A = \frac{3(q-1)^{-1/(1+r)}\Gamma(\frac{3}{2+2r})\Gamma(q-\frac{3}{2+2r})}{2\Gamma(\frac{5}{2+2r})\Gamma(q-\frac{5}{2+2r})}
$$
(2)

and  $V_{th} = \sqrt{A(2k_BT)/m}$  is the modified thermal velocity,  $\Gamma$  is the gamma function, *m* is the particle's mass, *T* is the particle's temperature in thermal equilibrium and  $k_B$  is the Boltzmann constant.

In recent times, there has been an increasing trend to use another power law distribution which is based on Tsallis statistics, known as non-extensive *Q*-distribution, which in the limit *Q*→1 reduces to Maxwellian distribution [\[39\].](#page-8-0) The non-extensive *Q*-distribution also shows flat top as well as Gaussian peak at low energies similar to  $(r, q)$  distribution, that is why we are going to employ both of these distributions in our study and present a comparison between these two. The threedimensional non-extensive *Q*-distribution has the form [40–[42\]](#page-8-0) 

$$
f_Q(v) = B \left( 1 - [Q - 1] \frac{v^2}{v_{th}^2} \right)^{\frac{1}{Q - 1}}
$$
 (3)

where

$$
B = \frac{\Gamma\left(\frac{1}{1-Q}\right)}{\Gamma\left(\frac{1}{1-Q} - \frac{3}{2}\right)} \left[\frac{1-Q}{\pi v_{th}^2}\right]^{3/2} \text{ for } \frac{1}{3} < Q \le 1
$$
 (4)

$$
B = \frac{3Q - 1}{2} \frac{\Gamma\left(\frac{1}{Q-1} + \frac{3}{2}\right)}{\Gamma\left(\frac{1}{Q-1}\right)} \left[\frac{Q-1}{\pi v_m^2}\right]^{3/2} \text{ for } Q \ge 1
$$
 (5)

and  $v_{th} = \sqrt{\frac{2k_BT}{m}}$  is the thermal velocity. In [Fig. 1](#page-2-0), we plot the  $(r, q)$ and non-extensive *Q*-distributions for different values of spectral indices *r*, *q* and *Q*-parameter. From [Fig. 1](#page-2-0)(a), we can see that for  $Q < 1$  and  $r < 0$ , both the distributions exhibit excess of superthermal particles with a Gaussian peak for *Q*-distribution and spiky peak for  $(r, q)$  distribution. However, for  $Q > 1$ , the *Q*-distribution exhibits smaller number of high energy particles as compared to the Maxwellian distribution and for  $r > 0$ , the  $(r, q)$  distribution exhibits flat top or shoulders at low velocities which becomes more prominent as  $r$  increases ([Fig. 1](#page-2-0)(b)). For comparison, kappa and Maxwellian distributions are also given in [Fig. 1](#page-2-0).

In most of the earlier studies, fluid treatment of magnetosonic waves was based on the assumption that the plasma is in thermal equilibrium and the pressure can be calculated by the ideal gas equation  $p = nk_BT$ , where *n* is the total number density and *T* is the particle's temperature. In the context of kinetic theory, pressure is defined as  $p = \frac{1}{3}$ *nm*  $\langle v^2 \rangle$ , where  $\langle v^2 \rangle$  is the mean square velocity of the particle, given as  $\langle v^2 \rangle$  $=\frac{1}{n}$  $\int f(v) d^3v$ . The mean square velocity of the particle for the cases of (*r*<sub>*,*</sub> *q*) and non-extensive *Q*-distribution can thus be calculated, respectively, as [\[42](#page-8-0)–43]

$$
\langle v^2 \rangle_{rq} = \frac{(q-1)^{\frac{1}{1+r}} \Gamma\left(\frac{s}{2+2r}\right) \Gamma\left(q - \frac{s}{2+2r}\right)}{\Gamma\left(\frac{3}{2+2r}\right) \Gamma\left(q - \frac{s}{2+2r}\right)} \frac{2k_B T}{m}
$$
(6)

and

$$
\langle v^2 \rangle_Q = \frac{3}{5Q - 3} \frac{2k_B T}{m} \tag{7}
$$

We can note that the standard expression of mean square velocity can be recovered from the above Eqs. (6) and (7) in the limits  $r = 0, q \rightarrow \infty$  and  $Q\rightarrow1$ , respectively. Thus the ideal gas equation for the cases of  $(r, q)$  and non-extensive *Q*-distributions can be written as

$$
p_{rq} = \frac{1}{3}nm < v^2 >_{rq} = \frac{1}{3}nm \frac{\left(q-1\right)^{\frac{1}{1+r}} \left(\frac{5}{2+2r}\right) \Gamma\left(q - \frac{5}{2+2r}\right)}{\Gamma\left(\frac{3}{2+2r}\right) \Gamma\left(q - \frac{3}{2+2r}\right)} \frac{2k_B T}{m} = n k_B T_{rq}
$$
\n(8)

$$
p_Q = \frac{1}{3}nm < v^2 > \frac{1}{2}nm\frac{3}{5Q-3}\frac{2k_B T}{m} = n k_B T_Q \tag{9}
$$

where

$$
T_{rq} = \frac{2(q-1)^{\frac{1}{1+r}}\Gamma\left(\frac{5}{2+2r}\right)\Gamma\left(q-\frac{5}{2+2r}\right)}{3\Gamma\left(\frac{3}{2+2r}\right)\Gamma\left(q-\frac{3}{2+2r}\right)}T\tag{10}
$$

and

$$
T_Q = \frac{2}{5Q - 3}T\tag{11}
$$

are the modified temperatures representing the  $(r, q)$ -distributed and *Q*-distributed plasmas, whereas *T* is the temperature representing the system in thermal equilibrium. In the limit  $Q \rightarrow 1$ ,  $T_Q$  approaches to *T* [43–[46\]](#page-8-0), for  $r = 0, q \rightarrow (\kappa + 1), T_{rq}$  becomes  $T_{\kappa} = \frac{2\kappa}{2\kappa - 3}T$  which is the modified temperature for *κ*-distributed plasma  $46-48$  and for  $r = 0$ , *q*→∞,  $T_{rq}$  becomes *T*. It should be noted that to keep  $T_Q$ ,  $T_{rq}$  and  $T_k$ 

<span id="page-2-0"></span>

Fig. 1. Non-extensive O-distribution (blue lines),  $(r, q)$ -distribution (red lines) and limiting forms of  $(r, q)$ -distribution, i.e. kappa (black thin line) and Maxwellian (black bold line) distributions for (a)  $Q < 1$  and  $r < 0$  and (b)  $Q > 1$  and  $r > 0$ . (For interpretation of the references to colour in this figure legend, the reader is referred to the web version of this article.)

positive, conditions  $Q > 3/5$ ,  $q > 1$ and $q(r+1) > 5/2$ , and  $\kappa > 3/2$ , respectively, should be satisfied [28 43,47].

To the best of the author's knowledge, obliquely propagating magnetosonic wave in a hot, dissipative nonthermal plasma has never been studied by deriving Kadomstev-Petvashvilli-Burger (KPB) equation. Hence, in this paper, we study the linear and nonlinear propagation of slow and fast magnetosonic wave modes in nonthermal plasma and derive the KPB equation. The effects of modified temperatures are investigated on the linear and nonlinear propagation of both the slow

and fast magnetosonic wave modes. The foremost aim of this paper is to present the set of nonlinear equations for the hot, dissipative nonthermal plasma by incorporating the different nonthermal distributions, which would be used to describe the two-dimensional magnetosonic waves and provide the basis for future study.

#### **Basic equations**

We consider a magnetized plasma in which the ambient magnetic

<span id="page-3-0"></span>field  $\mathbf{B}_0$  lies in the  $(x,y)$  plane making an angle  $\theta$  with the *x*-axis and propagation in the (*x*,z) plane with propagation vector *k* making an angle *φ* with the *x*-axis. In order to derive the KPB equation, we write the one-fluid magnetohydrodynamic (MHD) equations for an isotropic, isothermal non-Maxwellian plasma [\[1,49](#page-8-0)–50]. The mass conservation equation is

$$
\frac{\partial \rho}{\partial t} + \nabla \cdot (\rho \mathbf{v}) = 0 \tag{12}
$$

Equations of motion for ions and electrons, respectively, are

$$
m_i n_i \frac{dv_i}{dt} = n_i eE + \frac{e}{c} n_i (v_i \times B) - \nabla p_i + \lambda \nabla^2 v_i
$$
\n(13)

$$
m_e n_e \frac{d\mathbf{v}_e}{dt} = -n_e e \mathbf{E} - \frac{e}{c} n_e (\mathbf{v}_e \times \mathbf{B}) - \nabla p_e
$$
 (14)

By considering electrons as inertialess  $(m_e = 0)$  and using the quasineutrality condition  $n_i \approx n_e$ , above Eqs. [\(13\) and \(14\)](#page-1-0) can be solved to get the one fluid equation of motions as

$$
\rho \frac{dv}{dt} = \frac{1}{c} (\mathbf{j} \times \mathbf{B}) - \nabla p_e + \lambda \nabla^2 v_i
$$
\n(15)

In the above equation, we considered  $\nabla p_i = 0$  for  $T_i \ll T_e$  which is true for most of the space plasmas,  $v = v_i$  is the hydrodynamic velocity,  $j =$  $en(v_i - v_e)$ ,  $m_i + m_e \approx m_i$ ,  $\rho = m_i n_i$ ,  $p_e = n k_B T_a$  is the pressure where  $\alpha =$ *rq, Q* and  $\frac{d}{dt} = (\frac{\partial}{\partial t} + v \cdot \nabla)$ .

Now multiply Eq. (13) by  $m_i$  and Eq. (14) by  $m_e$  and subtracting Eq. (14) by Eq. (13), and neglecting the  $\frac{d}{dt}$  for slow motions where inertial effects are unimportant, we obtain the generalized Ohm's law as

$$
E = -\frac{v \times B}{c} + \frac{m_i}{4\pi \rho e} j \times B - \frac{m_i}{\rho e} \nabla p_e + \frac{m_i \lambda \nabla^2 v_i}{\rho e}
$$
(16)

The Maxwell's curl equations are

$$
\nabla \times \boldsymbol{E} = -\frac{1}{c} \frac{\partial \boldsymbol{B}}{\partial t} \tag{17}
$$

$$
\nabla \times \boldsymbol{B} = \frac{4\pi}{c} \boldsymbol{J} \tag{18}
$$

Upon using Eq.  $(18)$  into (15), we obtain

$$
\frac{dv}{dt} = \frac{1}{\rho} (\nabla \times \mathbf{B}) \times \mathbf{B} - \frac{\beta}{\rho} \nabla p_e + \lambda \nabla^2 v_i
$$
 (19)

By eliminating  $E$  from Eq.  $(16)$  using  $(17)$ , we get

$$
\frac{\partial \boldsymbol{B}}{\partial t} = \nabla \times (\boldsymbol{v} \times \boldsymbol{B}) - \frac{1}{\rho} \nabla \times [(\nabla \times \boldsymbol{B}) \times \boldsymbol{B}]
$$
\n(20)

In the above Eqs.  $(12)$ ,  $(19)$  and  $(20)$ , normalizations are taken as:  $\nu=\nu/\nu_A, B=B/B_o,\rho=\rho/\rho_0, p=P/p_o, \nabla=\nabla(\frac{\Omega_i}{\nu_A}), t=t/_{\Omega_i^{-1}}, \lambda=\lambda(\frac{\Omega_i}{\nu_A^2})$ is the kinematic viscosity, where  $\rho_0 = m_i n_0$ ,  $\Omega_i = \frac{e B_o}{m_i c}$  and  $\nabla^2 =$  $\frac{\partial^2}{\partial x^2} + \frac{\partial^2}{\partial z^2}$ . We note that  $\beta = c_s^2 / v_A^2$  contains all the nonthermal features, where  $c'_{s} = (T_{a}/m_{i})^{1/2}$  is the modified acoustic speed,  $T_{a}$  is the modified temperature given in Eqs. [\(10\) and \(11\),](#page-1-0) and  $v_A = B_0 / \sqrt{4\pi \rho_0}$  is the Alfven speed.

## **Derivation of KPB equation**

#### *Linear dispersion relation*

Using the standard reductive perturbation method  $[1,51-53]$  $[1,51-53]$ , we derive the KPB equation to study nonlinear magnetosonic waves propagating in two dimensions. We expand the various fluctuating quantities in dimensionless form with respect to small quantity  $\epsilon$ , that measures

the weakness of nonlinearity, as

$$
\rho = 1 + \epsilon \rho_1 + \epsilon^2 \rho_2 + \cdots
$$
  
\n
$$
v_x = \epsilon v_{x1} + \epsilon^2 v_{x2} + \cdots
$$
  
\n
$$
v_y = \epsilon v_{y1} + \epsilon^2 v_{y2} + \cdots
$$
  
\n
$$
v_z = \epsilon^{\frac{3}{2}} v_{z1} + \epsilon^{\frac{5}{2}} v_{z2} + \cdots
$$
  
\n
$$
B_x = \cos \theta
$$
  
\n
$$
B_y = \sin \theta + \epsilon B_{y1} + \epsilon^2 B_{y2} + \cdots
$$
  
\n
$$
B_z = \epsilon^{\frac{3}{2}} B_{z1} + \epsilon^{\frac{5}{2}} B_{z2} + \cdots
$$
  
\n(21)

and the stretched variables are introduced, as

$$
\xi = \epsilon^{\frac{1}{2}}(x - Vt)
$$
  
\n
$$
\eta = \epsilon_{\bar{x}}
$$
  
\n
$$
\tau = \epsilon^{\frac{3}{2}}t
$$
  
\n
$$
\lambda = \epsilon^{\frac{1}{2}}\nu
$$
\n(22)

where  $V = V_p / v_A$  is the normalized phase velocity.

Upon using Eqs.  $(21)$  and  $(22)$  into set of Eqs.  $(12)$  to  $(20)$ , and equating terms in lowest order of  $\epsilon$ , we obtain the first order equations as

$$
V \frac{\partial \rho_1}{\partial \xi} - \frac{\partial v_{x1}}{\partial \xi} = 0
$$
  
\n
$$
V \frac{\partial v_{x1}}{\partial \xi} = \beta \frac{\partial \rho_1}{\partial \xi} + \sin \theta \frac{\partial B_{y1}}{\partial \xi}
$$
  
\n
$$
V \frac{\partial v_{y1}}{\partial \xi} = -\cos \theta \frac{\partial B_{y1}}{\partial \xi}
$$
  
\n
$$
\frac{\partial B_{y1}}{\partial \xi} = \sin \theta \frac{\partial v_{x1}}{\partial \xi} - \cos \theta \frac{\partial v_{y1}}{\partial \xi}
$$
  
\n(23)

From the above set of Eqs.  $(23)$ , we obtain the linear quantities, as

$$
v_{x1} = \left(\frac{V\sin\theta}{(V^2 - \beta)}\right) B_{y1}
$$
  
\n
$$
v_{y1} = \left(\frac{\cos\theta}{V}\right) B_{y1}
$$
  
\n
$$
\rho_1 = \left(\frac{\sin\theta}{(V^2 - \beta)}\right) B_{y1}
$$
\n(24)

which results in linear dispersion relation (LDR) for magnetosonic waves propagating in two dimensions, as

$$
V^{2} = \frac{1+\beta'}{2} \left[ 1 \pm \left( 1 - \frac{4\beta'cos^{2}\theta}{(1+\beta')^{2}} \right)^{\frac{1}{2}} \right]
$$
 (25)

In the above LDR, fast magnetosonic mode in the super Alfvenic regime is represented by the upper sign (+) and slow magnetosonic mode in the sub-Alfvenic regime is represented by the lower sign (-). It should be noted that if  $\theta = 90°$  and the propagation is considered along *x*-axis, i.e.  $\varphi = 0$  in Eq. (25), LDR represents the pure magnetosonic wave for the case of fast mode. However, if  $\theta = 0^\circ$  and the propagation is again considered along *x*-axis, i.e.  $\varphi = 0$  in Eq. (25), LDR represents the pure Alfven wave for the fast mode and represents sound waves for the slow mode.

[Fig. 2](#page-4-0) depicts the linear phase velocity  $V = V_p / v_A$  against the angle  $\theta$ for fast mode (FM) as well as slow mode (SM) for non-extensive *Q*-distribution,  $(r, q)$ -distribution and limiting forms of  $(r, q)$ -distribution, i.e. kappa and Maxwellian distributions. Fig.  $2(a)$  and  $2(b)$  are plotted for *Q <* 1 and *r <* 0, in which we can see that phase velocity for FM increases but for SM decreases with *θ*. We can also note that for the FM ([Fig. 2](#page-4-0)(a)) as well as for the SM (Fig. 2(b)), the phase velocity is highest

*V*

<span id="page-4-0"></span>

**Fig. 2.** (a) and (b) depict the linear phase velocity *V* vs. *θ* for fast and slow modes, respectively, when  $Q = 0.65$  (dashed blue line),  $Q = 0.9$  (solid blue line),  $r =$  $-0.1$ ,  $q = 5$  (dashed red line),  $r = -0.31$ ,  $q = 5$  (solid red line). (c) and (d) depict the linear phase velocity V vs.  $\theta$  for fast and slow modes, respectively, when  $Q = 1.1$ (dashed blue line),  $Q = 1.4$  (solid blue line),  $r = 1$ ,  $q = 2$  (dashed red line),  $r = 4$ ,  $q = 2$  (solid red line). In Fig. 2(a)-(d), thin black line represents kappa distribution (*κ* = 2) and bold black line represents Maxwellian distribution. (For interpretation of the references to colour in this figure legend, the reader is referred to the web version of this article.)

for  $(r, q)$ -distribution  $(r = -0.31, q = 5)$  exhibiting maximum spiky distribution with high energy tail and least for Maxwellian (Fig. 2(a) and 2(b)). Fig. 2(c) and (d) are plotted for  $Q > 1$  and  $r > 0$ , in which for the FM we can see that phase velocity increases with *θ* but for SM it decreases with *θ*. We can also note that for the FM (Fig. 2(c) as well as for the SM (Fig. 2(d)), the phase velocity is highest for *κ*-distribution ( $\kappa$  = 2) exhibiting maximum high energy tail and least for  $(r, q)$ -distribution  $(r = 4, q = 2)$  showing broader shoulders at low energies.

#### *Nonlinear treatment*

In order to develop KP equation for both slow and fast modes, we write the  $\epsilon^2$  and  $\epsilon^{5/2}$  order terms using Eqs. [\(11\) and \(12\)](#page-1-0) into Eqs. [\(1\)](#page-1-0), (9) and (10), respectively, and get

$$
V\frac{\partial v_{z1}}{\partial \xi} = \sin\theta \frac{\partial B_{y1}}{\partial \eta} - \cos\theta \frac{\partial B_{z1}}{\partial \xi} + \beta \frac{\partial \rho_1}{\partial \eta}
$$
  

$$
V\frac{\partial B_{z1}}{\partial \xi} = -\cos\theta \frac{\partial v_{z1}}{\partial \xi} + \cos\theta \frac{\partial^2 B_{y1}}{\partial \xi^2}
$$
 (26)

and

$$
\frac{\partial \rho_1}{\partial t} + \rho_1 \frac{\partial v_{x1}}{\partial \xi} + v_{x1} \frac{\partial \rho_1}{\partial \xi} + \frac{\partial v_{z1}}{\partial \eta} = V \frac{\partial \rho_2}{\partial \xi} - \frac{\partial v_{x2}}{\partial \xi}
$$
\n
$$
\frac{\partial v_{x1}}{\partial t} + v_{x1} \frac{\partial v_{x1}}{\partial \xi} - \beta' \rho_1 \frac{\partial \rho_1}{\partial \xi} + B_{y1} \frac{\partial B_{y1}}{\partial \xi} - \rho_1 \sin \theta \frac{\partial B_{y1}}{\partial \xi}
$$
\n
$$
= V \frac{\partial v_{x2}}{\partial \xi} - \beta \frac{\partial \rho_2}{\partial \xi} - \sin \theta \frac{\partial B_{y2}}{\partial \xi}
$$
\n
$$
\frac{\partial v_{y1}}{\partial t} + v_{x1} \frac{\partial v_{y1}}{\partial \xi} + \cos \theta \rho_1 \frac{\partial B_{y1}}{\partial \xi} - \nu \frac{\partial^2 v_{y1}}{\partial \xi^2} = V \frac{\partial v_{y2}}{\partial \xi} + \cos \theta \frac{\partial B_{y2}}{\partial \xi}
$$
\n
$$
\frac{\partial B_{y1}}{\partial t} + B_{y1} \frac{\partial v_{x1}}{\partial \xi} + B_{u1} \frac{\partial B_{y1}}{\partial \xi} + \sin \theta \frac{\partial v_{z1}}{\partial \eta} - \cos \theta \frac{\partial^2 B_{z1}}{\partial \xi^2}
$$
\n
$$
= V \frac{\partial B_{y2}}{\partial \xi} + \cos \theta \frac{\partial v_{y2}}{\partial \xi} - \sin \theta \frac{\partial v_{x2}}{\partial \xi}
$$
\n(27)

From the Eqs. [\(14\) and \(17\),](#page-3-0) we get the following equations.

$$
\frac{\partial B_{z1}}{\partial \xi} = \frac{V^2 \cos\theta \sin\theta}{\left(\cos^2\theta - V^2\right) \left(V^2 - \beta\right)} \frac{\partial B_{y1}}{\partial \eta} - \frac{V \cos\theta}{\left(\cos^2\theta - V^2\right)} \frac{\partial^2 B_{y1}}{\partial \xi^2}
$$
(28)

$$
\frac{\partial v_{z1}}{\partial \xi} = -\frac{V^3 \sin \theta}{\left(\cos^2 \theta - V^2\right) \left(V^2 - \beta\right)} \frac{\partial B_{y1}}{\partial \eta} + \frac{\cos^2 \theta}{\left(\cos^2 \theta - V^2\right)} \frac{\partial^2 B_{y1}}{\partial \xi^2}
$$
(29)

Rather monotonous but simple algebraic operations leads to the following KPB equation.

$$
\frac{\partial}{\partial \xi} \left[ \frac{\partial B_{y1}}{\partial \tau} + C B_{y1} \frac{\partial B_{y1}}{\partial \xi} - D \frac{\partial^2 B_{y1}}{\partial \xi^2} + E \frac{\partial^3 B_{y1}}{\partial \xi^3} \right] + F \frac{\partial^2 B_{y1}}{\partial \eta^2} = 0 \tag{30}
$$

where,  $C = b/a$ ,  $D = c/a$ ,  $E = d/a$ ,  $F = e/a$ , and

<span id="page-5-0"></span>
$$
a = \frac{1}{V^2(V^2 - \beta)^2} [V^6 + V^4(1 - 2\beta) + V^2\beta (1 - 3\cos^2\theta + \beta) + \beta^2 \cos^2\theta]
$$
  
\n
$$
b = \frac{\sin\theta}{(V^2 - \beta)^3} [3V^5 - V\beta (6V^2 - 3\beta - 2\sin^2\theta)]
$$
  
\n
$$
c = \frac{-V^4 + \beta (2V^2 - \beta)\cos^2\theta}{V^2(V^2 - \beta)^2} V
$$
  
\n
$$
d = \frac{V\cos^2\theta}{(\cos^2\theta - V^2)}
$$
  
\n
$$
e = \frac{V^5 \sin^2\theta}{(V^2 - \cos^2\theta)(V^2 - \beta)^2}
$$

Equation [\(30\)](#page-4-0) is a nonlinear partial differential equation that contains both dispersion and dissipation for which the most efficient and convenient method to solve such equation is the tanh method [\[53](#page-8-0)–55]. In our model, we considered viscosity, however, if we add collisions in our model we get non-stationary solutions, e.g. Raut et al. [\[56\]](#page-9-0) derived the damped forced KP equation using the reductive perturbation method to obtain the non-stationary solitary solution for ion acoustic waves. Therefore, the solution of Eq. [\(30\)](#page-4-0) using the tanh method, can be written as [\[57\]](#page-9-0) 

$$
B_{y} = \frac{6D^{2}}{25CE} \left[ 1 - \tanh\left(\frac{D}{10E}\chi\right) \right] + \frac{3D^{2}}{25CE} \left[ \operatorname{sech}^{2}\left(\frac{D}{10E}\chi\right) \right]
$$
(31)

where we have assumed  $B_y = B_{y1}$ . Also in the above solution,  $\chi = (k_{\xi} \xi +$  $k_{\eta}$ η −Ω*τ*), where  $\Omega = \frac{6D^2}{25E} + F$  is the frequency of nonlinear structure,  $k_{\xi} =$ *k*cos $\varphi$  and  $k_n = k \sin \varphi$ . The solution Eq. (31) of KPB equation [\(30\)](#page-4-0) is for fast and slow modes of magnetosonic waves and valid for  $k_{\xi} > k_{\eta}$  only as the stretched variable *ξ* is of lower order than the coordinate *η* given in Eq.  $(22)$ . We note that the structure of the KP equation  $(30)$  is the same in the current manuscript and in Maxwellian plasma, however, the only difference is in the definition of  $\beta$ <sup>'</sup> which contains all the nonthermal features, and in the Maxwellian limit  $\beta \rightarrow \beta$  [\[1,10\].](#page-8-0)

## **Numerical solution**

In this section, we plot the solution (Eq.(31)) of KPB equation for different values of spectral indices  $Q$ ,  $(r, q)$  and kinematic viscosity  $\nu$ . Fig. 3 depicts the shock profiles of FM and SM magnetosonic wave for different distributions. Fig. 3(a) and (b) represent the FM rarefactive and SM compressive shock profiles, respectively for  $Q<1$  and  $r<0.$  We can see that the strength and steepness of FM shock profile is maximum for  $(r, q)$ -distribution  $(r = -0.4, q = 5)$  and least for Maxwellian whereas the strength and steepness of SM shock profile is maximum for Maxwellian and least for  $(r, q)$ -distribution  $(r = -0.4, q = 5)$ . A comparison of Fig. 3(a) and 3(b) shows that the non-Maxwellian FM shocks are steeper than the SM shocks but have less shock strength. Fig. 3(c) and 3 (d) represent the FM rarefactive and SM compressive shock profiles, respectively for  $Q > 1$  and  $r > 0$ . We can see that strength and steepness of FM shock profile are maximum for *κ*-distribution (*κ* = 2) and least for  $(r, q)$ -distribution  $(r = 4, q = 2)$  whereas strength and steepness of SM

**Fig. 3.** (a) and (b) depict the fast mode rarefactive and slow mode compressive shock profiles, respectively, when *Q* = 0*.*65 (dashed blue line), *Q* = 0*.*9 (solid blue line),  $r = -0.1$ ,  $q = 5$  (dashed red line),  $r = -0.4$ ,  $q = 5$  (solid red line). (c) and (d) depict the fast mode rarefactive and slow mode compressive shock profiles, respectively, when  $Q = 1.1$  (dashed blue line),  $Q = 1.4$  (solid blue line),  $r = 1$ ,  $q = 2$  (dashed red line),  $r = 4$ ,  $q = 2$  (solid red line). In Fig. 3(a)-(d),  $\nu = 0.02$ ,  $\theta =$ 80*<sup>o</sup>*, thin black line represents kappa distribution (*κ* = 2) and bold black line represents Maxwellian distribution. (For interpretation of the references to colour in this figure legend, the reader is referred to the web version of this article.)

shock profile are maximum for  $(r, q)$ -distribution  $(r = 4, q = 2)$  and least for *κ*-distribution ( $\kappa = 2$ ). Comparison of [Fig. 3\(](#page-5-0)c) and 3(d) shows that the SM shocks are much steeper and have more shock strength than the FM shocks.

Fig. 4 depicts the shock strength for different values of spectral indices  $r < 0$ ,  $Q < 1$  and kinematic viscosity  $\nu$  but for a fixed value of  $\chi$ . Fig. 4(a) and (b) portray the shock strength of FM and SM shock profiles, respectively, for  $r < 0$ . In Fig. 4(a), we can see that shock strength increases with *ν*, however, it increases much faster with *ν* when the distribution becomes more spiky, i.e.*r*→ − 0*.*4 than it becomes less spiky, i.  $e.r \rightarrow -0.1$ . In Fig. 4(b), we can see that shock strength increases with *ν*, however, it increases much faster with *ν* when the distribution becomes less spiky, i.e.*r*→ − 0*.*1 than it becomes more spiky, i.e.*r*→ − 0*.*4. Fig. 4(c) and (d) portray the shock strengths of FM and SM shock profiles, respectively, for  $Q < 1$ . In Fig. 4(c), we can see that shock strength increases with *ν*, however, it increases much faster when the distribution contains high energy tail, i.e. $Q\rightarrow 0.64$  than the distribution when it tends to become Maxwellian, i.e. $Q\rightarrow 1$ . In Fig. 4(d), we can see that shock strength increases with  $\nu$ , however, it increases much faster when the distribution tends to become Maxwellian, i.e.*Q*→1 than the distribution when it contains high energy tail, i.e.*Q*→0*.*64. Comparison of Fig. 4(a) and  $4(c)$  shows that the FM shock strength is higher for  $(r, q)$ -distribution than for *Q*-distribution for the same values of  $\nu$ , however, for Fig. 4(b) and 4(d), SM shock strength is higher for *Q*-distribution than for  $(r, q)$ -distribution for the same values of  $\nu$ . The shaded areas in Fig. 4 represent the values for which the solution becomes non-physical, i.e.

 $|B_{y1}| > 1$ . It is also noted that as the viscosity increases, the amplitude of the soliton increases but the width of the shock front decreases which is evident in [Fig. 3.](#page-5-0)

[Fig. 5](#page-7-0) depicts the shock strength of the shock profiles for different values of spectral indices *r >* 0, *Q >* 1 and kinematic viscosity *ν* but for fixed value of  $\chi$ . [Fig. 5\(](#page-7-0)a) and 5(b) portray the shock strength of FM and SM shock profiles, respectively, for *r >* 0. We can see that shock strength increases with  $\nu$  for FM ([Fig. 5\(](#page-7-0)a)) as well as for SM [\(Fig. 5\(](#page-7-0)b)), however, it increases much faster with  $\nu$  for SM when the distribution exhibits conspicuous shoulders, i.e. $r\rightarrow$ 4 [\(Fig. 5](#page-7-0)(b)). We can also note that shock strength remains almost the same for the change in  $r$  [\(Fig. 5\(](#page-7-0)a)). [Fig. 5\(](#page-7-0)c) and (d) portray the shock strength of FM and SM shock profiles, respectively, for *Q >* 1. We can see that shock strength increases with *ν*  for FM (Fig.  $5(c)$ ) as well as for SM (Fig.  $5(d)$ ), however, it increases much faster with *ν* for SM when the distribution exhibits a broader Gaussian peak with a smaller number of high energy particles as compared to Maxwellian, i.e. $Q \rightarrow 1.4$  [\(Fig. 5\(](#page-7-0)d)). It can also be noted that shock strength for FM almost remains the same for the change in *Q*  ([Fig. 5](#page-7-0)(c)). Comparison of [Fig. 5\(](#page-7-0)a) and 5(c) shows that the FM shock strength is almost the same for (*r, q*)- as well as for *Q*-distributions for the same values of  $\nu$ , however, for [Fig. 5\(](#page-7-0)b) and 5(d) tells us that SM shock strength is lower for *Q*-distribution than for  $(r, q)$ -distribution for the same values of *ν*. Again it can be noted that as the viscosity increases, the amplitude of the soliton increases but the width of the shock front decreases which is evident in [Fig. 3.](#page-5-0)

**Fig. 4.** (a) and (b) depict the variation of shock strength of fast mode rarefactive and slow mode compressive shock profiles for  $(r, q)$ -distribution, respectively, for different values of negative *r* and *ν* but fixed value of *χ*. (c) and (d) depict the variation of shock strength of fast mode rarefactive and slow mode compressive shock profiles for non-extensive *Q*-distribution, respectively, for different values of *Q* < 1 and *ν* but fixed value of *χ*. In Fig. 4(a)-(d),  $θ = 80°$ .

<span id="page-7-0"></span>

**Fig. 5.** (a) and (b) depict the variation of shock strength of fast mode rarefactive and slow mode compressive shock profiles for  $(r, q)$ -distribution, respectively, for different values of positive *r* and *ν* but fixed value of *χ*. (c) and (d) depict the variation of shock strength of fast mode rarefactive and slow mode compressive shock profiles for non-extensive *Q*-distribution, respectively, for different values of  $Q > 1$  and  $\nu$  but fixed value of  $\chi$ . In Fig. 5(a)-(d),  $\theta = 80°$ .

#### **Summary and conclusion**

We derived the LDR and KPB equation for slow and fast magnetosonic wave modes in nonthermal plasmas. Fro  $Q < 1$  and  $r < 0$ , linear phase velocity for FM as well as for SM remains highest for  $(r, q)$ -distribution showing maximum peak at low energies and least for the Maxwellian. For  $Q > 1$  and  $r > 0$ , the linear phase velocity for both fast and slow modes is highest for *κ*-distribution exhibiting high energy tail and maximum peak at low energies and least for  $(r, q)$ -distribution exhibiting flat top or broader shoulders at low energies. For the nonlinear propagation, when  $Q < 1$  and  $r < 0$ , we found that the strength and steepness of FM shock profile is maximum for  $(r, q)$ -distribution exhibiting spiky nature at low energies and least for the Maxwellian whereas strength and steepness of SM shock profile is maximum for the Maxwellian and least for  $(r, q)$ -distribution having spiky nature at low energies. For  $Q > 1$  and  $r > 0$ , the strength and steepness of FM shock profile is maximum for *κ*-distribution exhibiting maximum peak at low energies as well as high energy tail and least for (*r, q*)-distribution having flat top at low energies whereas strength and steepness of SM shock profile is maximum for  $(r, q)$ -distribution with flat top and least for *κ*-distribution. The dependence of shock strength on the kinematic viscosity  $\nu$  is also studied. It is found that the shock strength for both the fast and slow modes increases with the increase in *ν* for all the distributions.

This paper presented the investigations on the obliquely propagating fast and slow magnetosonic wave modes in a hot nonthermal plasma by

incorporating the modified temperatures derived from non-extensive *Q*-distribution, (*r, q*)-distribution and limiting forms of (*r, q*)-distribution, i.e. kappa and Maxwellian distributions. For the case of *Q <* 1 and *r <* 0, we found that low energy particles are responsible for the increase in the FM as well as SM linear phase velocities whereas for the case of *Q >* 1 and *r >* 0, high energy particles are responsible for the increase in the FM as well as SM linear phase velocities. For the nonlinear propagation, we found that distribution with both the peak at low energies as well as high energy tail are responsible for the increase in steepness and strength of FM shock profile, however, for the SM shock profiles a distribution with more low energy particles having broader shoulders or Gaussian peak is responsible for the increase in steepness and strength. We also found that the shock amplitude increases with the kinematic viscosity for all distributions. We note here that the main aim of this manuscript is to investigate the effect of nonthermal distribution functions on the propagation of slow and fast mode shock structures. Our numerical results are general since we have used the normalized parameters, so we can apply our results to any region of space and astrophysical plasmas. For example, if we consider the observations of magnetosonic waves near the Earth's magnetic equatorial plane, for which  $B_0 = 10nT$ ,  $n_0 = 0.25$ *cm*<sup>-3</sup> and  $\beta = 0.5$  [\[58\],](#page-9-0) the shock strength for fast mode ranges from 0*.*035*nT* to 0*.*12*nT* and for slow mode, it ranges from 0.35*nT* to 0.83*nT* when  $\nu = 0.02$ . By increasing the value of viscosity, shock amplitude can also be increased to match the observational values. We, thus found that linear as well as nonlinear propagation of slow and fast magnetosonic wave modes are significantly altered

<span id="page-8-0"></span>in the non-Maxwellian plasmas in which nonthermality is incorporated by taking into account the modified temperatures.
